Devices

Platforms

Spring 2016 – Exploring new territory

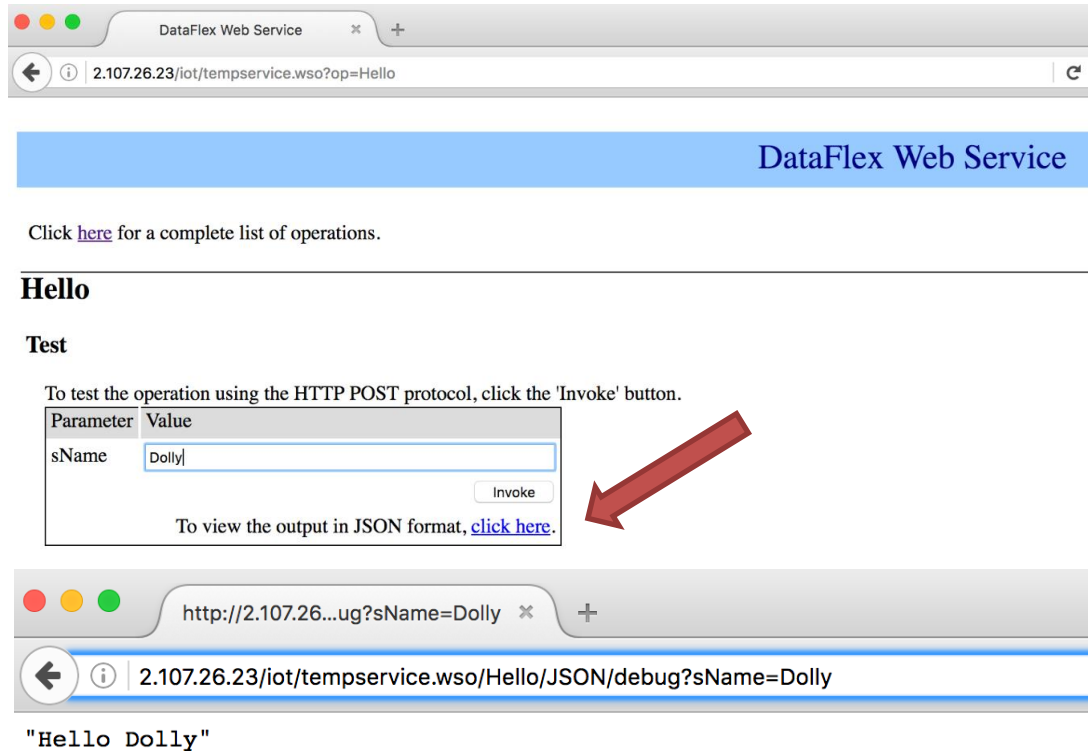

Why DataFlex and IoT?

To be or not to be? Which is the lesser evil?

To program a SOAP client in c
Or to program a REST-service in DataFlex?
As it turns out DataFlex already does REST.

REST service in DF

The screenshot shows a web browser window titled "DataFlex Web Service". The address bar displays the URL `2.107.26.23/iot/tempervice.wso?op=Hello`. Below the browser window, a blue header bar contains the text "DataFlex Web Service".

Click [here](#) for a complete list of operations.

Hello

Test

To test the operation using the HTTP POST protocol, click the 'Invoke' button.

Parameter	Value
sName	<input type="text" value="Dolly"/>

To view the output in JSON format, [click here](#).

Below the test form, another browser window is shown with the URL `http://2.107.26...ug?sName=Dolly` in the tab and `2.107.26.23/iot/tempervice.wso/Hello/JSON/debug?sName=Dolly` in the address bar. The response displayed is `"Hello Dolly"`.

DataFlex Web Service

Sensor (C/C++)

```
client.println("GET /Arduino/tempService.wso/Hello/JSON/debug?sName=Dolly HTTP/1.1");  
client.println("Host: 192.168.1.63");  
client.println();
```

Server (DataFlex)

Object oHello is a cWebService

```
{ Published=True }  
{ Description="" }
```

```
Procedure Hello String sName Returns String  
    Function_Return ("Hello " + sName)  
End_Procedure
```

End_Object

Micro Controllers; What are they?

- A Micro Controller or MCU is a small programmable device with a lot of analogous and digital connectors.
- It can do a set of simple repetitive tasks – Fast
- In recent years MCU's and WiFi chips are build together.

How to start

ARDUINO UNO

WeMos D1 mini

ESP8266 12E

Why Arduino

- It is a de-facto standard.
- Easy to work with.
- Are referenced to by all producers of MCU's and sensors.
- IDE (Big word for small program) works for most other MCU's

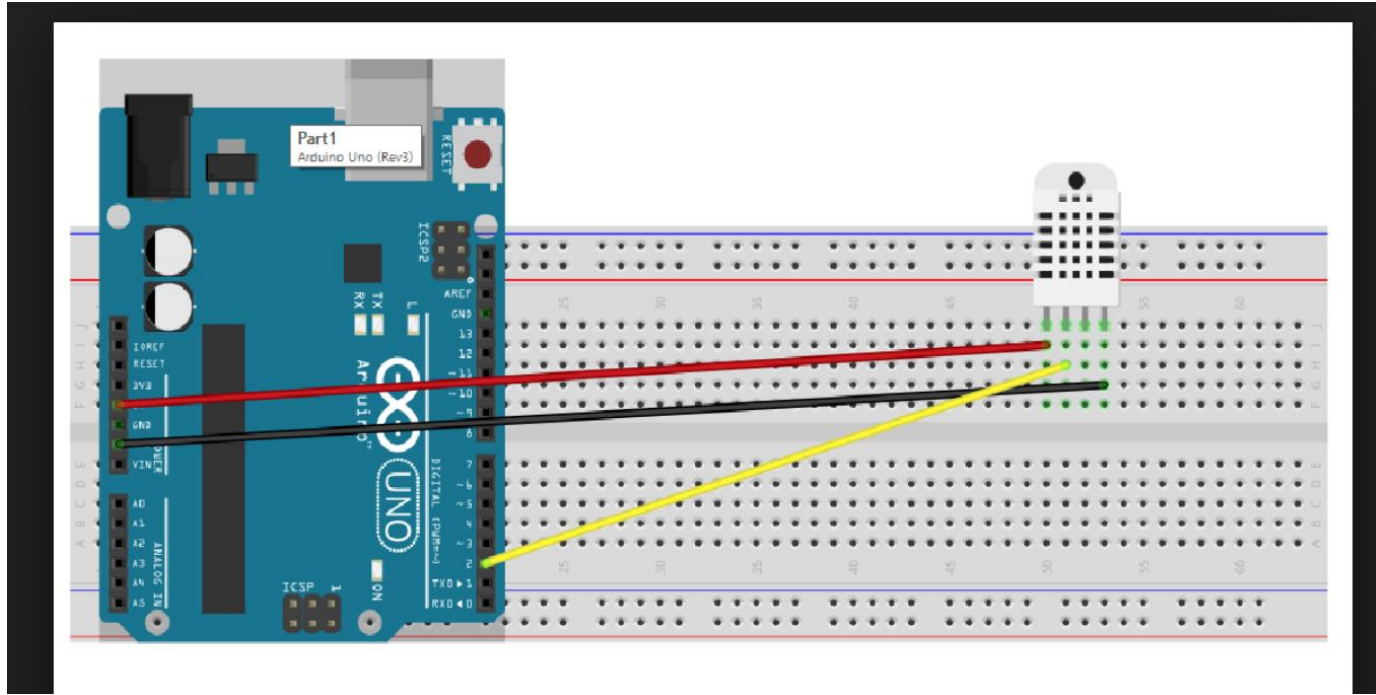

The Arduino IDE

The screenshot shows the Arduino IDE interface with a file named 'restclient' open. The code is written in C++ and demonstrates how to use the `WiFiClient` library to connect to a web server. The code includes headers for `SPI`, `WiFi`, and a custom `RestClient.h`. It defines SSID and password variables, sets the server IP to 2.107.26.23, and implements a `setup` function to initialize the serial port and WiFi. The `loop` function attempts to connect to the server on port 80 and sends a GET request to a specific URL. If the connection fails, it restarts the ESP module.

```
restclient | Arduino 1.6.8
restclient $
1 #include <SPI.h>
2 #include <WiFi.h>
3 #include "RestClient.h"
4
5 char ssid[] = "xxx";
6 char pass[] = "xxx";
7 int status = WL_IDLE_STATUS;
8
9 IPAddress server(2,107,26,23);
10
11 WiFiClient client;
12
13 void setup() {
14   Serial.begin(9600);
15   WiFi.begin(ssid, pass);
16   IPAddress ip = WiFi.localIP();
17   Serial.println(ip);
18   Serial.println("connecting...");
19
20   if (client.connect(server, 80)) {
21     Serial.println("connected");
22     client.println("GET /Arduino/tempService.wso/Hello/JSON/debug?sName=Dolly HTTP/1.1");
23     client.println("Host: 2.107.26.23");
24     client.println();
25   } else {
26     // No connection
27     Serial.println("connection failed.");
28     ESP.restart();
29   }
30 }
31
32 void loop() {
33 }
```

How to connect a sensor?

How to get information?

If the vendor does not have the information you need: Google it!

Arduino DHT22 (AM2302) Tutorial + Library + Wiring
www.electroschematics.com/.../arduino-dht22-am2302-tutorial-lib... ▼ Oversæt denne side
You can use the DHT22 (or AM2302) humidity/temperature sensor and the Arduino UNO board to read data and print it out to the serial monitor or to display i.

A business case - Light

My only job is to check if the light is turned on or off and report that to a DataFlex webservice.

This tells you how much energy you have saved by switching to LED.
